

# ミクロ計量経済

**Mon., 8:50-10:20**

**Room # 509 (法経研究棟)**

- The prerequisite of this class is **Basic Statistics** (統計基礎) and **Econometrics** (エコノメトリックス) (undergraduate level, next semester, 『計量経済学』 山本 拓 著, 新世社).
- The class of **Introductory Econometrics** (計量経済学基礎) should be registered.

# **Statistics Test (統計検定) on Nov. 29 (Sun.)**

- **Exams :** Level 1 (1 級) – Level 4 (4 級)

Note that Level 4 is Junior high school level,

Level 3 is High school level, and

Level 2 is the 1st or 2nd year statistics in undergraduate school.

Level 1 is the 3rd or 4th year statistics in undergraduate school (or the 1st year in graduate school).

See <http://www.toukei-kentei.jp/> in more detail.

- **Qualification for Exam (受験資格) :**

Undergraduate and Graduate Students in Osaka University

- **Application Period** (受験申込期間) : September 9 (Wed.), AM10:00 — October 14 (Wed.), PM15:00

Go to <http://qajss.org/jinse/kentei201511.html> for application.

- **Application Fee** (受験料) : Free

受験料は、平成24年度に採択された文部科学省の大学間連携共同推進事業「データに基づく課題解決型人材育成に資する統計教育質保証」から支払われる。

連携校： 東京大学, 大阪大学, 総合研究大学院大学, 青山学院大学（代表校）, 多摩大学, 立教大学, 早稲田大学, 同志社大学

ちなみに、連携大学以外の人の受験料は、

1級「統計数理」	10:30～12:00	6,000円
1級「統計応用」	13:30～15:00	6,000円
2級	10:30～12:00	5,000円
3級	13:30～14:30	4,000円
4級	10:30～11:30	3,000円
統計調査士	13:00～14:30	5,000円
専門統計調査士	10:30～12:00	10,000円

となる。ただし、1級「統計数理」と「統計応用」の両方受験の場合、受験料は10,000円となる。

- **Exam Date (試験日) :** Nov. 29 (Sun.)
- **Exam Place (場所) :** 人間科学研究科  
本館（44講義室）・東館（303, 404講義室）

## 予定

1. 最小二乗法（復讐）

2. 最尤法（復讐）

3. 質的データ

4. パネルデータ

5. .....

# 1 最小二乗法について

経済理論に基づいた線型モデルの係数の値をデータから求める時に用いられる手法  $\Rightarrow$  最小二乗法

## 1.1 最小二乗法と回帰直線

$(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$  のように  $n$  組のデータがあり、 $X_i$  と  $Y_i$  との間に以下の線型関係を想定する。

$$Y_i = \alpha + \beta X_i,$$

$X_i$  は説明変数、 $Y_i$  は被説明変数、 $\alpha, \beta$  はパラメータとそれぞれ呼ばれる。

上の式は回帰モデル(または、回帰式)と呼ばれる。目的は、切片  $\alpha$  と傾き  $\beta$  をデータ  $\{(X_i, Y_i), i = 1, 2, \dots, n\}$  から推定すること、

データについて：

1. タイム・シリーズ(時系列)・データ： $i$  が時間を表す(第  $i$  期)。
2. クロス・セクション(横断面)・データ： $i$  が個人や企業を表す(第  $i$  番目の家計，第  $i$  番目の企業)。

## 1.2 切片 $\alpha$ と傾き $\beta$ の推定

次のような関数  $S(\alpha, \beta)$  を定義する。

$$S(\alpha, \beta) = \sum_{i=1}^n u_i^2 = \sum_{i=1}^n (Y_i - \alpha - \beta X_i)^2$$

このとき，

$$\min_{\alpha, \beta} S(\alpha, \beta)$$

となるような  $\alpha, \beta$  を求める(最小自乗法)。このときの解を  $\widehat{\alpha}, \widehat{\beta}$  とする。

最小化のためには,

$$\frac{\partial S(\alpha, \beta)}{\partial \alpha} = 0$$

$$\frac{\partial S(\alpha, \beta)}{\partial \beta} = 0$$

を満たす  $\alpha, \beta$  が  $\widehat{\alpha}, \widehat{\beta}$  となる。 すなわち,  $\widehat{\alpha}, \widehat{\beta}$  は,

$$\sum_{i=1}^n (Y_i - \widehat{\alpha} - \widehat{\beta}X_i) = 0, \quad (1)$$

$$\sum_{i=1}^n X_i(Y_i - \widehat{\alpha} - \widehat{\beta}X_i) = 0, \quad (2)$$

を満たす。 さらに,

$$\sum_{i=1}^n Y_i = n\widehat{\alpha} + \widehat{\beta} \sum_{i=1}^n X_i, \quad (3)$$

$$\sum_{i=1}^n X_i Y_i = \widehat{\alpha} \sum_{i=1}^n X_i + \widehat{\beta} \sum_{i=1}^n X_i^2,$$

行列表示によって,

$$\begin{pmatrix} \sum_{i=1}^n Y_i \\ \sum_{i=1}^n X_i Y_i \end{pmatrix} = \begin{pmatrix} n & \sum_{i=1}^n X_i \\ \sum_{i=1}^n X_i & \sum_{i=1}^n X_i^2 \end{pmatrix} \begin{pmatrix} \widehat{\alpha} \\ \widehat{\beta} \end{pmatrix},$$

逆行列の公式 :

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$$

$\widehat{\alpha}, \widehat{\beta}$ について, まとめて,

$$\begin{aligned} \begin{pmatrix} \widehat{\alpha} \\ \widehat{\beta} \end{pmatrix} &= \begin{pmatrix} n & \sum_{i=1}^n X_i \\ \sum_{i=1}^n X_i & \sum_{i=1}^n X_i^2 \end{pmatrix}^{-1} \begin{pmatrix} \sum_{i=1}^n Y_i \\ \sum_{i=1}^n X_i Y_i \end{pmatrix} \\ &= \frac{1}{n \sum_{i=1}^n X_i^2 - (\sum_{i=1}^n X_i)^2} \begin{pmatrix} \sum_{i=1}^n X_i^2 & -\sum_{i=1}^n X_i \\ -\sum_{i=1}^n X_i & n \end{pmatrix} \begin{pmatrix} \sum_{i=1}^n Y_i \\ \sum_{i=1}^n X_i Y_i \end{pmatrix} \end{aligned}$$

さらに,  $\widehat{\beta}$ について解くと,

$$\widehat{\beta} = \frac{n \sum_{i=1}^n X_i Y_i - (\sum_{i=1}^n X_i)(\sum_{i=1}^n Y_i)}{n \sum_{i=1}^n X_i^2 - (\sum_{i=1}^n X_i)^2}$$

$$= \frac{\sum_{i=1}^n X_i Y_i - n \overline{X} \overline{Y}}{\sum_{i=1}^n X_i^2 - n \overline{X}^2} = \frac{\sum_{i=1}^n (X_i - \overline{X})(Y_i - \overline{Y})}{\sum_{i=1}^n (X_i - \overline{X})^2}$$

連立方程式の(3)式から、

$$\widehat{\alpha} = \overline{Y} - \widehat{\beta} \overline{X}$$

となる。ただし、

$$\overline{X} = \frac{1}{n} \sum_{i=1}^n X_i, \quad \overline{Y} = \frac{1}{n} \sum_{i=1}^n Y_i,$$

とする。

**数値例：** 以下の数値例を使って、回帰式  $Y_i = \alpha + \beta X_i$  の  $\alpha$ ,  $\beta$  の推定値  $\widehat{\alpha}$ ,  $\widehat{\beta}$  を求める。

$i$	$Y_i$	$X_i$
1	6	10
2	9	12
3	10	14
4	10	16

$\hat{\alpha}$ ,  $\hat{\beta}$  を求めるための公式は

$$\hat{\beta} = \frac{\sum_{i=1}^n X_i Y_i - n \overline{X} \overline{Y}}{\sum_{i=1}^n X_i^2 - n \overline{X}^2}$$

$$\hat{\alpha} = \overline{Y} - \hat{\beta} \overline{X}$$

なので、必要なものは  $\overline{X}$ ,  $\overline{Y}$ ,  $\sum_{i=1}^n X_i^2$ ,  $\sum_{i=1}^n X_i Y_i$  である。

$i$	$Y_i$	$X_i$	$X_i Y_i$	$X_i^2$
1	6	10	60	100
2	9	12	108	144
3	10	14	140	196
4	10	16	160	256
合計	$\sum Y_i$	$\sum X_i$	$\sum X_i Y_i$	$\sum X_i^2$
	35	52	468	696
平均	$\bar{Y}$	$\bar{X}$		
	8.75	13		

よって、

$$\hat{\beta} = \frac{468 - 4 \times 13 \times 8.75}{696 - 4 \times 13^2} = \frac{13}{20} = 0.65$$

$$\hat{\alpha} = 8.75 - 0.65 \times 13 = 0.3$$

となる。

## 注意事項 :

1.  $\alpha, \beta$  は真の値で未知
2.  $\widehat{\alpha}, \widehat{\beta}$  は  $\alpha, \beta$  の推定値でデータから計算される

回帰直線は

$$\widehat{Y}_i = \widehat{\alpha} + \widehat{\beta}X_i,$$

として与えられる。

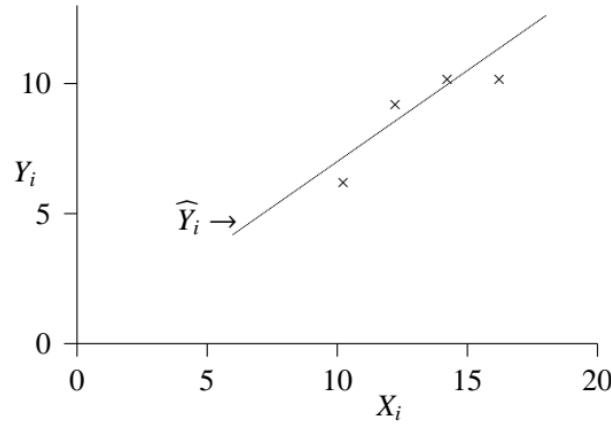

上の数値例では,

$$\widehat{Y}_i = 0.3 + 0.65X_i$$

となる。

$i$	$Y_i$	$X_i$	$X_i Y_i$	$X_i^2$	$\widehat{Y}_i$
1	6	10	60	100	6.8
2	9	12	108	144	8.1
3	10	14	140	196	9.4
4	10	16	160	256	10.7
合計	$\sum Y_i$	$\sum X_i$	$\sum X_i Y_i$	$\sum X_i^2$	$\sum \widehat{Y}_i$
	35	52	468	696	35.0
平均	$\bar{Y}$	$\bar{X}$			
	8.75	13			

図 2 :  $Y_i$ ,  $X_i$ ,  $\widehat{Y}_i$

$\widehat{Y}_i$  を実績値  $Y_i$  の予測値または理論値と呼ぶ。

$$\widehat{u}_i = Y_i - \widehat{Y}_i,$$

$\widehat{u}_i$  を残差と呼ぶ。

$$Y_i = \widehat{Y}_i + \widehat{u}_i = \widehat{\alpha} + \widehat{\beta}X_i + \widehat{u}_i,$$

さらに、 $\overline{Y}$  を両辺から引いて、

$$(Y_i - \overline{Y}) = (\widehat{Y}_i - \overline{Y}) + \widehat{u}_i,$$

### 1.3 残差 $\widehat{u}_i$ の性質について

$\widehat{u}_i = Y_i - \widehat{\alpha} - \widehat{\beta}X_i$  に注意して、(1) 式から、

$$\sum_{i=1}^n \widehat{u}_i = 0,$$

を得る。 (2) 式から、

$$\sum_{i=1}^n X_i \widehat{u}_i = 0,$$

を得る。  $\widehat{Y}_i = \widehat{\alpha} + \widehat{\beta}X_i$  から,

$$\sum_{i=1}^n \widehat{Y}_i \widehat{u}_i = 0,$$

を得る。なぜなら,

$$\begin{aligned}\sum_{i=1}^n \widehat{Y}_i \widehat{u}_i &= \sum_{i=1}^n (\widehat{\alpha} + \widehat{\beta}X_i) \widehat{u}_i \\ &= \widehat{\alpha} \sum_{i=1}^n \widehat{u}_i + \widehat{\beta} \sum_{i=1}^n X_i \widehat{u}_i \\ &= 0\end{aligned}$$

である。

$i$	$Y_i$	$X_i$	$\widehat{Y}_i$	$\widehat{u}_i$	$X_i \widehat{u}_i$	$\widehat{Y}_i \widehat{u}_i$
1	6	10	6.8	-0.8	-8.0	-5.44
2	9	12	8.1	0.9	10.8	7.29
3	10	14	9.4	0.6	8.4	5.64
4	10	16	10.7	-0.7	-11.2	-7.49
合計	$\sum Y_i$	$\sum X_i$	$\sum \widehat{Y}_i$	$\sum \widehat{u}_i$	$\sum X_i \widehat{u}_i$	$\sum \widehat{Y}_i \widehat{u}_i$
	35	52	35.0	0.0	0.0	0.00

## 1.4 決定係数 $R^2$ について

次の式

$$(Y_i - \bar{Y}) = (\widehat{Y}_i - \bar{Y}) + \widehat{u}_i,$$

の両辺を二乗して、総和すると、

$$\begin{aligned}\sum_{i=1}^n (Y_i - \bar{Y})^2 &= \sum_{i=1}^n ((\widehat{Y}_i - \bar{Y}) + \widehat{u}_i)^2 \\&= \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2 + 2 \sum_{i=1}^n (\widehat{Y}_i - \bar{Y}) \widehat{u}_i + \sum_{i=1}^n \widehat{u}_i^2 \\&= \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2 + \sum_{i=1}^n \widehat{u}_i^2\end{aligned}$$

となる。まとめると、

$$\sum_{i=1}^n (Y_i - \bar{Y})^2 = \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2 + \sum_{i=1}^n \widehat{u}_i^2$$

を得る。さらに、

$$1 = \frac{\sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} + \frac{\sum_{i=1}^n \widehat{u}_i^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2}$$

それぞれの項は、

1.  $\sum_{i=1}^n (Y_i - \bar{Y})^2 \Rightarrow y$  の全変動
2.  $\sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2 \Rightarrow \hat{Y}_i$  (回帰直線) で説明される部分
3.  $\sum_{i=1}^n \hat{u}_i^2 \Rightarrow \hat{Y}_i$  (回帰直線) で説明されない部分

となる。

回帰式の当てはまりの良さを示す指標として、決定係数  $R^2$  を以下の通りに定義する。

$$R^2 = \frac{\sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2}$$

または、

$$R^2 = 1 - \frac{\sum_{i=1}^n \hat{u}_i^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2},$$

として書き換えられる。

または,  $Y_i = \widehat{Y}_i + \widehat{u}_i$  と

$$\begin{aligned}\sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2 &= \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})(Y_i - \bar{Y} - \widehat{u}_i) \\&= \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})(Y_i - \bar{Y}) - \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})\widehat{u}_i \\&= \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})(Y_i - \bar{Y})\end{aligned}$$

を用いて,

$$\begin{aligned}R^2 &= \frac{\sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} \\&= \frac{\left(\sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2\right)^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2 \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2} \\&= \left( \frac{\sum_{i=1}^n (\widehat{Y}_i - \bar{Y})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^n (Y_i - \bar{Y})^2 \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2}} \right)^2\end{aligned}$$

と書き換えられる。すなわち,  $R^2$  は  $Y_i$  と  $\widehat{Y}_i$  の相関係数の二乗と解釈される。

$$\sum_{i=1}^n (Y_i - \bar{Y})^2 = \sum_{i=1}^n (\widehat{Y}_i - \bar{Y})^2 + \sum_{i=1}^n \widehat{u}_i^2 \text{ から, 明らかに,}$$

$$0 \leq R^2 \leq 1,$$

となる。 $R^2$  が 1 に近づけば回帰式の当てはまりは良いと言える。しかし,  $t$  分布のような数表は存在しない。したがって、「どの値よりも大きくなるべき」というような基準はない。

慣習的には, メドとして 0.9 以上を判断基準にする。

数値例： 決定係数の計算には以下の公式を用いる。

$$R^2 = 1 - \frac{\sum_{i=1}^n \widehat{u}_i^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} = 1 - \frac{\sum_{i=1}^n \widehat{u}_i^2}{\sum_{i=1}^n Y_i^2 - n\bar{Y}^2}$$

計算に必要なものは、 $\widehat{u}_i = Y_i - (\widehat{\alpha} + \widehat{\beta}X_i)$ ,  $\overline{Y}$ ,  $\sum_{i=1}^n Y_i^2$  である。

$i$	$Y_i$	$X_i$	$\widehat{Y}_i$	$\widehat{u}_i$	$\widehat{u}_i$	$Y_i^2$
1	6	10	6.8	-0.8	0.64	36
2	9	12	8.1	0.9	0.81	81
3	10	14	9.4	0.6	0.36	100
4	10	16	10.7	-0.7	0.49	100
合計	$\sum Y_i$	$\sum X_i$	$\sum \widehat{Y}_i$	$\sum \widehat{u}_i$	$\sum \widehat{u}_i^2$	$\sum Y_i^2$
	35	52	35.0	0.0	2.30	317

$\sum \widehat{u}_i^2 = 2.30$ ,  $\overline{X} = 13$ ,  $\overline{Y} = 8.75$ ,  $\sum_{i=1}^n Y_i^2 = 317$  なので,

$$R^2 = 1 - \frac{2.30}{317 - 4 \times 8.75^2} = 1 - \frac{2.30}{10.75} = 0.786$$

## 1.5 まとめ

$\hat{\alpha}$ ,  $\hat{\beta}$  を求めるための公式は

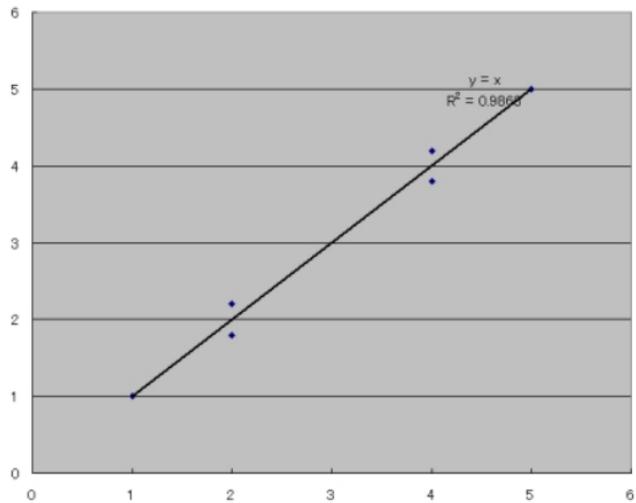

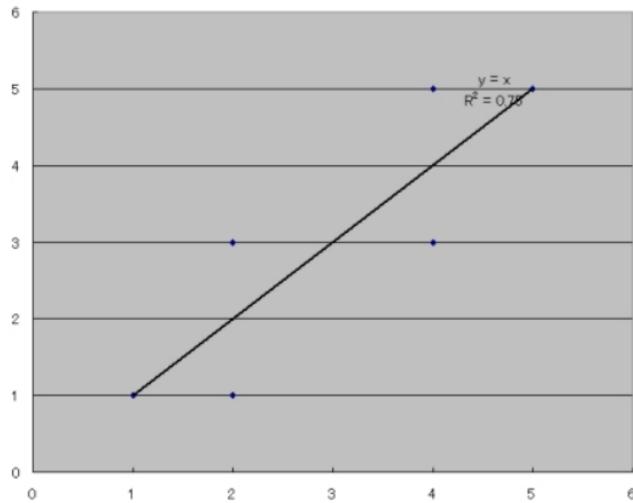

$$\begin{aligned}\hat{\beta} &= \frac{\sum_{i=1}^n X_i Y_i - n \bar{X} \bar{Y}}{\sum_{i=1}^n X_i^2 - n \bar{X}^2} \\ \hat{\alpha} &= \bar{Y} - \hat{\beta} \bar{X}\end{aligned}$$

なので、必要なものは  $\bar{X}$ ,  $\bar{Y}$ ,  $\sum_{i=1}^n X_i^2$ ,  $\sum_{i=1}^n X_i Y_i$  である。

決定係数の計算には以下の公式を用いる。

$$R^2 = 1 - \frac{\sum_{i=1}^n \hat{u}_i^2}{\sum_{i=1}^n (Y_i - \bar{Y})^2} = 1 - \frac{\sum_{i=1}^n \hat{u}_i^2}{\sum_{i=1}^n Y_i^2 - n \bar{Y}^2}$$

計算に必要なものは、 $\sum \hat{u}_i^2$ ,  $\bar{Y}$ ,  $\sum_{i=1}^n Y_i^2$  である。

## 2 Regression Analysis (回帰分析)

### 2.1 Setup of the Model

When  $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$  are available, suppose that there is a linear relationship between  $y$  and  $x$ , i.e.,

$$y_i = \beta_1 + \beta_2 x_i + u_i, \quad (4)$$

for  $i = 1, 2, \dots, n$ .  $x_i$  and  $y_i$  denote the  $i$ th observations.

→ Single (or simple) regression model (単回帰モデル)

$y_i$  is called the **dependent variable** (従属変数) or the **explained variable** (被説明変数), while  $x_i$  is known as the **independent variable** (独立変数) or the **explanatory (or explaining) variable** (説明変数).

$$\beta_1 = \text{Intercept} \text{ (切片)}, \quad \beta_2 = \text{Slope} \text{ (傾き)}$$

$\beta_1$  and  $\beta_2$  are unknown **parameters** (パラメータ, 母数) to be estimated.

$\beta_1$  and  $\beta_2$  are called the **regression coefficients** (回帰係数).

$u_i$  is the unobserved **error term** (誤差項) assumed to be a random variable with mean zero and variance  $\sigma^2$ .

$\sigma^2$  is also a parameter to be estimated.

$x_i$  is assumed to be **nonstochastic** (非確率的), but  $y_i$  is **stochastic** (確率的) because  $y_i$  depends on the error  $u_i$ .

The error terms  $u_1, u_2, \dots, u_n$  are assumed to be mutually independently and identically distributed, which is called **iid**.

It is assumed that  $u_i$  has a distribution with mean zero, i.e.,  $E(u_i) = 0$  is assumed.

Taking the expectation on both sides of (4), the expectation of  $y_i$  is represented as:

$$\begin{aligned} E(y_i) &= E(\beta_1 + \beta_2 x_i + u_i) = \beta_1 + \beta_2 x_i + E(u_i) \\ &= \beta_1 + \beta_2 x_i, \end{aligned} \tag{5}$$

for  $i = 1, 2, \dots, n$ .

Using  $E(y_i)$  we can rewrite (4) as  $y_i = E(y_i) + u_i$ .

(5) represents the true regression line.

Let  $\hat{\beta}_1$  and  $\hat{\beta}_2$  be estimates of  $\beta_1$  and  $\beta_2$ .

Replacing  $\beta_1$  and  $\beta_2$  by  $\hat{\beta}_1$  and  $\hat{\beta}_2$ , (4) turns out to be:

$$y_i = \hat{\beta}_1 + \hat{\beta}_2 x_i + e_i, \tag{6}$$

for  $i = 1, 2, \dots, n$ , where  $e_i$  is called the **residual** (残差).

The residual  $e_i$  is taken as the experimental value (or realization) of  $u_i$ .

We define  $\hat{y}_i$  as follows:

$$\hat{y}_i = \hat{\beta}_1 + \hat{\beta}_2 x_i, \quad (7)$$

for  $i = 1, 2, \dots, n$ , which is interpreted as the **predicted value** (予測値) of  $y_i$ .

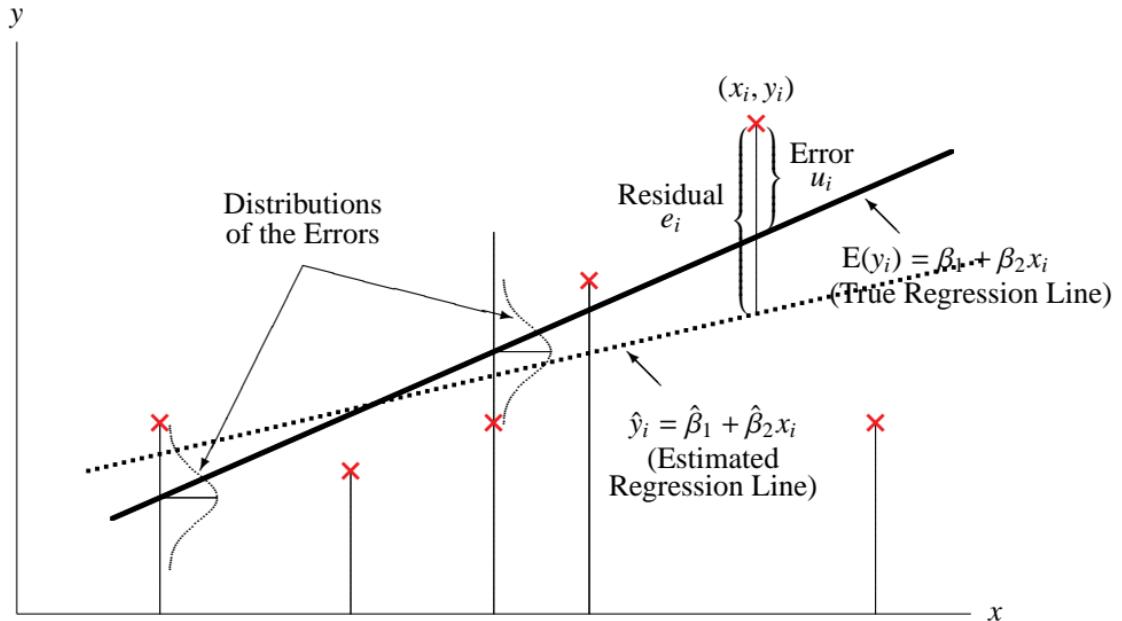

(7) indicates the estimated regression line, which is different from (5).

Moreover, using  $\hat{y}_i$  we can rewrite (6) as  $y_i = \hat{y}_i + e_i$ .

(5) and (7) are displayed in Figure 1.

Consider the case of  $n = 6$  for simplicity.  $\times$  indicates the observed data series.

**Figure 1. True and Estimated Regression Lines (回帰直線)**

The true regression line (5) is represented by the solid line, while the estimated regression line (7) is drawn with the dotted line.

Based on the observed data,  $\beta_1$  and  $\beta_2$  are estimated as:  $\hat{\beta}_1$  and  $\hat{\beta}_2$ .

In the next section, we consider how to obtain the estimates of  $\beta_1$  and  $\beta_2$ , i.e.,  $\hat{\beta}_1$  and  $\hat{\beta}_2$ .

## 2.2 Ordinary Least Squares Estimation

Suppose that  $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$  are available.

For the regression model (4), we consider estimating  $\beta_1$  and  $\beta_2$ .

Replacing  $\beta_1$  and  $\beta_2$  by their estimates  $\hat{\beta}_1$  and  $\hat{\beta}_2$ , remember that the residual  $e_i$  is given by:

$$e_i = y_i - \hat{y}_i = y_i - \hat{\beta}_1 - \hat{\beta}_2 x_i.$$

The sum of squared residuals is defined as follows:

$$S(\hat{\beta}_1, \hat{\beta}_2) = \sum_{i=1}^n e_i^2 = \sum_{i=1}^n (y_i - \hat{\beta}_1 - \hat{\beta}_2 x_i)^2.$$

It might be plausible to choose the  $\hat{\beta}_1$  and  $\hat{\beta}_2$  which minimize the sum of squared residuals, i.e.,  $S(\hat{\beta}_1, \hat{\beta}_2)$ .

This method is called the **ordinary least squares estimation** (最小二乘法, **OLS**).

To minimize  $S(\hat{\beta}_1, \hat{\beta}_2)$  with respect to  $\hat{\beta}_1$  and  $\hat{\beta}_2$ , we set the partial derivatives equal to zero:

$$\frac{\partial S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_1} = -2 \sum_{i=1}^n (y_i - \hat{\beta}_1 - \hat{\beta}_2 x_i) = 0,$$

$$\frac{\partial S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_2} = -2 \sum_{i=1}^n x_i(y_i - \hat{\beta}_1 - \hat{\beta}_2 x_i) = 0.$$

The second order condition for minimization is:

$$\begin{pmatrix} \frac{\partial^2 S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_1^2} & \frac{\partial^2 S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_1 \partial \hat{\beta}_2} \\ \frac{\partial^2 S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_2 \partial \hat{\beta}_1} & \frac{\partial^2 S(\hat{\beta}_1, \hat{\beta}_2)}{\partial \hat{\beta}_2^2} \end{pmatrix} = \begin{pmatrix} 2n & 2 \sum_{i=1}^n x_i \\ 2 \sum_{i=1}^n x_i & 2 \sum_{i=1}^n x_i^2 \end{pmatrix}$$

should be a positive definite matrix.

The diagonal elements  $2n$  and  $2 \sum_{i=1}^n x_i^2$  are positive.

The determinant:

$$\begin{vmatrix} 2n & 2 \sum_{i=1}^n x_i \\ 2 \sum_{i=1}^n x_i & 2 \sum_{i=1}^n x_i^2 \end{vmatrix} = 4n \sum_{i=1}^n x_i^2 - 4 \left( \sum_{i=1}^n x_i \right)^2 = 4n \sum_{i=1}^n (x_i - \bar{x})^2$$

is positive.  $\implies$  The second-order condition is satisfied.

The first two equations yield the following two equations:

$$\bar{y} = \hat{\beta}_1 + \hat{\beta}_2 \bar{x}, \tag{8}$$

$$\sum_{i=1}^n x_i y_i = n \bar{x} \hat{\beta}_1 + \hat{\beta}_2 \sum_{i=1}^n x_i^2, \tag{9}$$

where  $\bar{y} = \frac{1}{n} \sum_{i=1}^n y_i$  and  $\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$ .

Multiplying (8) by  $n\bar{x}$  and subtracting (9), we can derive  $\hat{\beta}_2$  as follows:

$$\hat{\beta}_2 = \frac{\sum_{i=1}^n x_i y_i - n\bar{x}\bar{y}}{\sum_{i=1}^n x_i^2 - n\bar{x}^2} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2}. \quad (10)$$

From (8),  $\hat{\beta}_1$  is directly obtained as follows:

$$\hat{\beta}_1 = \bar{y} - \hat{\beta}_2 \bar{x}. \quad (11)$$

When the observed values are taken for  $y_i$  and  $x_i$  for  $i = 1, 2, \dots, n$ , we say that  $\hat{\beta}_1$  and  $\hat{\beta}_2$  are called the **ordinary least squares estimates** (or simply the **least squares estimates**, 最小二乘推定值) of  $\beta_1$  and  $\beta_2$ .

When  $y_i$  for  $i = 1, 2, \dots, n$  are regarded as the random sample, we say that  $\hat{\beta}_1$  and  $\hat{\beta}_2$  are called the **ordinary least squares estimators** (or the **least squares estimators**, 最小二乘推定量) of  $\beta_1$  and  $\beta_2$ .

## 2.3 Properties of Least Squares Estimator

Equation (10) is rewritten as:

$$\begin{aligned}\hat{\beta}_2 &= \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n (x_i - \bar{x})y_i}{\sum_{i=1}^n (x_i - \bar{x})^2} - \frac{\bar{y} \sum_{i=1}^n (x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2} \\ &= \sum_{i=1}^n \frac{x_i - \bar{x}}{\sum_{i=1}^n (x_i - \bar{x})^2} y_i = \sum_{i=1}^n \omega_i y_i.\end{aligned}\tag{12}$$

In the third equality,  $\sum_{i=1}^n (x_i - \bar{x}) = 0$  is utilized because of  $\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$ .

In the fourth equality,  $\omega_i$  is defined as:  $\omega_i = \frac{x_i - \bar{x}}{\sum_{i=1}^n (x_i - \bar{x})^2}$ .

$\omega_i$  is nonstochastic because  $x_i$  is assumed to be nonstochastic.

$\omega_i$  has the following properties:

$$\sum_{i=1}^n \omega_i = \sum_{i=1}^n \frac{x_i - \bar{x}}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n (x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2} = 0,\tag{13}$$

$$\sum_{i=1}^n \omega_i x_i = \sum_{i=1}^n \omega_i (x_i - \bar{x}) = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} = 1, \quad (14)$$

$$\sum_{i=1}^n \omega_i^2 = \sum_{i=1}^n \left( \frac{x_i - \bar{x}}{\sum_{i=1}^n (x_i - \bar{x})^2} \right)^2 = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{\left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2} = \frac{1}{\sum_{i=1}^n (x_i - \bar{x})^2}. \quad (15)$$

The first equality of (14) comes from (13).

From now on, we focus only on  $\hat{\beta}_2$ , because usually  $\beta_2$  is more important than  $\beta_1$  in the regression model (4).

In order to obtain the properties of the least squares estimator  $\hat{\beta}_2$ , we rewrite (12) as:

$$\begin{aligned} \hat{\beta}_2 &= \sum_{i=1}^n \omega_i y_i = \sum_{i=1}^n \omega_i (\beta_1 + \beta_2 x_i + u_i) \\ &= \beta_1 \sum_{i=1}^n \omega_i + \beta_2 \sum_{i=1}^n \omega_i x_i + \sum_{i=1}^n \omega_i u_i = \beta_2 + \sum_{i=1}^n \omega_i u_i. \end{aligned} \quad (16)$$

In the fourth equality of (16), (13) and (14) are utilized.

## [Review] Random Variables:

Let  $X_1, X_2, \dots, X_n$  be  $n$  random variables, which are mutually independently and identically distributed.

**mutually independent**  $\implies f(x_i, x_j) = f_i(x_i)f_j(x_j)$  for  $i \neq j$ .

$f(x_i, x_j)$  denotes a joint distribution of  $X_i$  and  $X_j$ .

$f_i(x)$  indicates a marginal distribution of  $X_i$ .

**identical**  $\implies f_i(x) = f_j(x)$  for  $i \neq j$ .

**[End of Review]**

## [Review] Mean and Variance:

Let  $X$  and  $Y$  be random variables (continuous type), which are independently distributed.

### Definition and Formulas:

- $E(g(X)) = \int g(x)f(x)dx$  for a function  $g(\cdot)$  and a density function  $f(\cdot)$ .
- $V(X) = E((X - \mu)^2) = \int (x - \mu)^2 f(x)dx$  for  $\mu = E(X)$ .
- $E(aX + b) = aE(X) + b$  and  $V(aX + b) = a^2V(X)$ .
- $E(X \pm Y) = E(X) \pm E(Y)$  and  $V(X \pm Y) = V(X) + V(Y)$ .

**[End of Review]**

**Mean and Variance of  $\hat{\beta}_2$ :**  $u_1, u_2, \dots, u_n$  are assumed to be mutually independently and identically distributed with mean zero and variance  $\sigma^2$ , but they are not necessarily normal.

Remember that we do not need normality assumption to obtain mean and variance but the normality assumption is required to test a hypothesis.

From (16), the expectation of  $\hat{\beta}_2$  is derived as follows:

$$E(\hat{\beta}_2) = E(\beta_2 + \sum_{i=1}^n \omega_i u_i) = \beta_2 + E(\sum_{i=1}^n \omega_i u_i) = \beta_2 + \sum_{i=1}^n \omega_i E(u_i) = \beta_2. \quad (17)$$

It is shown from (17) that the ordinary least squares estimator  $\hat{\beta}_2$  is an **unbiased estimator** (不偏推定量) of  $\beta_2$ .

From (16), the variance of  $\hat{\beta}_2$  is computed as:

$$\begin{aligned} V(\hat{\beta}_2) &= V(\beta_2 + \sum_{i=1}^n \omega_i u_i) = V\left(\sum_{i=1}^n \omega_i u_i\right) = \sum_{i=1}^n V(\omega_i u_i) = \sum_{i=1}^n \omega_i^2 V(u_i) \\ &= \sigma^2 \sum_{i=1}^n \omega_i^2 = \frac{\sigma^2}{\sum_{i=1}^n (x_i - \bar{x})^2}. \end{aligned} \tag{18}$$

The third equality holds because  $u_1, u_2, \dots, u_n$  are mutually independent.

The last equality comes from (15).

Thus,  $E(\hat{\beta}_2)$  and  $V(\hat{\beta}_2)$  are given by (17) and (18).

**Gauss-Markov Theorem** (ガウス・マルコフ定理):  $\hat{\beta}_2$  has minimum variance within a class of the linear unbiased estimators.

→ **best linear unbiased estimator (BLUE, 最良線型不偏推定量)**

(Proof is omitted.)

**Distribution of  $\hat{\beta}_2$ :** We discuss the small sample properties of  $\hat{\beta}_2$ .

In order to obtain the distribution of  $\hat{\beta}_2$  in small sample, the distribution of the error term has to be assumed.

Therefore, the extra assumption is that  $u_i \sim N(0, \sigma^2)$ .

Writing (16), again,  $\hat{\beta}_2$  is represented as:

$$\hat{\beta}_2 = \beta_2 + \sum_{i=1}^n \omega_i u_i.$$

First, we obtain the distribution of the second term in the above equation.

It is well known that sum of normal random variables results in a normal distribution.

Therefore,  $\sum_{i=1}^n \omega_i u_i$  is distributed as:

$$\sum_{i=1}^n \omega_i u_i \sim N\left(0, \sigma^2 \sum_{i=1}^n \omega_i^2\right).$$

Therefore,  $\hat{\beta}_2$  is distributed as:

$$\hat{\beta}_2 = \beta_2 + \sum_{i=1}^n \omega_i u_i \sim N(\beta_2, \sigma^2 \sum_{i=1}^n \omega_i^2),$$

or equivalently,

$$\frac{\hat{\beta}_2 - \beta_2}{\sigma \sqrt{\sum_{i=1}^n \omega_i^2}} = \frac{\hat{\beta}_2 - \beta_2}{\sigma / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \sim N(0, 1),$$

for any  $n$ .

Moreover, replacing  $\sigma^2$  by its estimator  $s^2 = \frac{1}{n-2} \sum_{i=1}^n (y_i - \hat{\beta}_1 - \hat{\beta}_2 x_i)^2$ , it is known that we have:

$$\frac{\hat{\beta}_2 - \beta_2}{s / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \sim t(n-2),$$

where  $t(n-2)$  denotes  $t$  distribution with  $n-2$  degrees of freedom.

Thus, under normality assumption on the error term  $u_i$ , the  $t(n - 2)$  distribution is used for the confidence interval and the testing hypothesis in small sample.

Or, taking the square on both sides,

$$\left( \frac{\hat{\beta}_2 - \beta_2}{s / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \right)^2 \sim F(1, n - 2).$$

## [Review] Confidence Interval (信頼区間, 区間推定)):

Suppose that  $X_1, X_2, \dots, X_n$  are mutually independently, identically and normally distributed with mean  $\mu$  and variance  $\sigma^2$ .

Then, we can obtain:  $\frac{\bar{X} - \mu}{S/\sqrt{n}} \sim t(n-1)$ , where  $S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2$ .

That is,

$$P\left(-t_{\alpha/2}(n-1) < \frac{\bar{X} - \mu}{S/\sqrt{n}} < t_{\alpha/2}(n-1)\right) = 1 - \alpha$$

i.e.,

$$P\left(\bar{X} - t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}}\right) = 1 - \alpha.$$

Note that  $t_{\alpha/2}(n-1)$  is obtained from the  $t$  distribution table, given  $\alpha$  and  $n-1$ .

Then, replacing  $\bar{X}$  by  $\bar{x}$ , we obtain the  $100(1-\alpha)\%$  confidence interval of  $\mu$  as follows:

$$\left(\bar{x} - t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}}, \bar{x} + t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}}\right).$$

## [End of Review]

In the case of OLS,

$$P\left(-t_{\alpha/2}(n-2) < \frac{\hat{\beta}_2 - \beta_2}{s/\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} < t_{\alpha/2}(n-2)\right) = 1 - \alpha,$$

where  $t_{\alpha/2}(n-2)$  denotes  $100 \times \alpha/2\%$  point from the  $t(n-2)$  distribution.

Rewriting,

$$P\left(\hat{\beta}_2 - t_{\alpha/2}(n-2) \frac{s}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} < \beta_2 < \hat{\beta}_2 + t_{\alpha/2}(n-2) \frac{s}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}\right) = 1 - \alpha.$$

Replacing  $\hat{\beta}_2$  and  $s^2$  by observed data, the  $100(1 - \alpha)\%$  confidence interval of  $\beta_2$  is given by:

$$\left(\hat{\beta}_2 - t_{\alpha/2}(n-2) \frac{s}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}, \hat{\beta}_2 + t_{\alpha/2}(n-2) \frac{s}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}\right).$$

## [Review] Testing the Hypothesis (仮説検定):

Suppose that  $X_1, X_2, \dots, X_n$  are mutually independently, identically and normally distributed with mean  $\mu$  and variance  $\sigma^2$ .

Then, we obtain:  $\frac{\bar{X} - \mu}{S/\sqrt{n}} \sim t(n-1)$ , where  $S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2$ , which is known as the unbiased estimator of  $\sigma^2$ .

- The null hypothesis  $H_0 : \mu = \mu_0$ , where  $\mu_0$  is a fixed number.
- The alternative hypothesis  $H_1 : \mu \neq \mu_0$

Under the null hypothesis, we have the distribution:  $\frac{\bar{X} - \mu_0}{S/\sqrt{n}} \sim t(n-1)$ .

Replacing  $\bar{X}$  and  $S^2$  by  $\bar{x}$  and  $s^2$ , compare  $\frac{\bar{x} - \mu_0}{s/\sqrt{n}}$  and  $t(n-1)$ .

$H_0$  is rejected when  $\left| \frac{\bar{x} - \mu_0}{s/\sqrt{n}} \right| > t_{\alpha/2}(n-1)$ .

$t_{\alpha/2}(n-1)$  is obtained from the significance level  $\alpha$  and the degrees of freedom  $n-1$ .

**[End of Review]**

In the case of OLS, the hypotheses are as follows:

- The null hypothesis  $H_0 : \beta_2 = \beta_2^*$
- The alternative hypothesis  $H_1 : \beta_2 \neq \beta_2^*$

Under  $H_0$ ,

$$\frac{\hat{\beta}_2 - \beta_2^*}{s / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \sim t(n-2).$$

Replacing  $\hat{\beta}_2$  and  $s^2$  by the observed data, compare  $\frac{\hat{\beta}_2 - \beta_2^*}{s / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}$  and  $t(n-2)$ .

$H_0$  is rejected at significance level  $\alpha$  when  $\left| \frac{\hat{\beta}_2 - \beta_2^*}{s / \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \right| > t_{\alpha/2}(n-1)$ .

(\*)  $\hat{\beta}_2$  = Coefficient,  $\frac{s}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}$  = Standard Error,  
 $s$  = Standard Error of Regression
