

**Example: MA( $q$ ) Model:**  $y_t = \epsilon_t + \theta_1\epsilon_{t-1} + \theta_2\epsilon_{t-2} + \cdots + \theta_q\epsilon_{t-q}$

**1. Mean of MA( $q$ ) Process:**

$$E(y_t) = E(\epsilon_t + \theta_1\epsilon_{t-1} + \theta_2\epsilon_{t-2} + \cdots + \theta_q\epsilon_{t-q}) = 0$$

**2. Autocovariance Function of MA( $q$ ) Process:**

$$\gamma(\tau) = \begin{cases} \sigma_\epsilon^2(\theta_0\theta_\tau + \theta_1\theta_{\tau+1} + \cdots + \theta_{q-\tau}\theta_q) = \sigma_\epsilon^2 \sum_{i=0}^{q-\tau} \theta_i\theta_{\tau+i}, & \tau = 1, 2, \dots, q, \\ 0, & \tau = q + 1, q + 2, \dots, \end{cases}$$

where  $\theta_0 = 1$ .

3. MA( $q$ ) process is stationary.

4. **MA( $q$ ) +drift:**  $y_t = \mu + \epsilon_t + \theta_1\epsilon_{t-1} + \theta_2\epsilon_{t-2} + \cdots + \theta_q\epsilon_{t-q}$

Mean:

$$y_t = \mu + \theta(L)\epsilon_t,$$

where  $\theta(L) = 1 + \theta_1L + \theta_2L^2 + \cdots + \theta_qL^q$ .

Therefore, we have:

$$E(y_t) = \mu + \theta(L)E(\epsilon_t) = \mu.$$

## 7.5 ARMA Model

ARMA (Autoregressive Moving Average, 自己回帰移動平均) Process

### 1. ARMA( $p, q$ )

$$y_t = \phi_1 y_{t-1} + \phi_2 y_{t-2} + \cdots + \phi_p y_{t-p} + \epsilon_t + \theta_1 \epsilon_{t-1} + \theta_2 \epsilon_{t-2} + \cdots + \theta_q \epsilon_{t-q},$$

which is rewritten as:

$$\phi(L)y_t = \theta(L)\epsilon_t,$$

where  $\phi(L) = 1 - \phi_1 L - \phi_2 L^2 - \cdots - \phi_p L^p$  and  $\theta(L) = 1 + \theta_1 L + \theta_2 L^2 + \cdots + \theta_q L^q$ .

### 2. Likelihood Function:

The variance-covariance matrix of  $Y$ , denoted by  $V$ , has to be computed.

**Example: ARMA(1,1) Process:**  $y_t = \phi_1 y_{t-1} + \epsilon_t + \theta_1 \epsilon_{t-1}$

Obtain the autocorrelation coefficient.

The mean of  $y_t$  is to take the expectation on both sides.

$$E(y_t) = \phi_1 E(y_{t-1}) + E(\epsilon_t) + \theta_1 E(\epsilon_{t-1}),$$

where the second and third terms are zeros.

Therefore, we obtain:

$$E(y_t) = 0.$$

The autocovariance of  $y_t$  is to take the expectation, multiplying  $y_{t-\tau}$  on both sides.

$$E(y_t y_{t-\tau}) = \phi_1 E(y_{t-1} y_{t-\tau}) + E(\epsilon_t y_{t-\tau}) + \theta_1 E(\epsilon_{t-1} y_{t-\tau}).$$

Each term is given by:

$$E(y_t y_{t-\tau}) = \gamma(\tau), \quad E(y_{t-1} y_{t-\tau}) = \gamma(\tau - 1),$$

$$E(\epsilon_t y_{t-\tau}) = \begin{cases} \sigma_\epsilon^2, & \tau = 0, \\ 0, & \tau = 1, 2, \dots, \end{cases} \quad E(\epsilon_{t-1} y_{t-\tau}) = \begin{cases} (\phi_1 + \theta_1)\sigma_\epsilon^2, & \tau = 0, \\ \sigma_\epsilon^2, & \tau = 1, \\ 0, & \tau = 2, 3, \dots \end{cases}$$

Therefore, we obtain;

$$\gamma(0) = \phi_1 \gamma(1) + (1 + \phi_1 \theta_1 + \theta_1^2) \sigma_\epsilon^2,$$

$$\gamma(1) = \phi_1 \gamma(0) + \theta_1 \sigma_\epsilon^2,$$

$$\gamma(\tau) = \phi_1 \gamma(\tau - 1), \quad \tau = 2, 3, \dots$$

From the first two equations,  $\gamma(0)$  and  $\gamma(1)$  are computed by:

$$\begin{pmatrix} 1 & -\phi_1 \\ -\phi_1 & 1 \end{pmatrix} \begin{pmatrix} \gamma(0) \\ \gamma(1) \end{pmatrix} = \sigma_\epsilon^2 \begin{pmatrix} 1 + \phi_1 \theta_1 + \theta_1^2 \\ \theta_1 \end{pmatrix}$$

$$\begin{pmatrix} \gamma(0) \\ \gamma(1) \end{pmatrix} = \sigma_\epsilon^2 \begin{pmatrix} 1 & -\phi_1 \\ -\phi_1 & 1 \end{pmatrix}^{-1} \begin{pmatrix} 1 + \phi_1 \theta_1 + \theta_1^2 \\ \theta_1 \end{pmatrix}$$

$$= \frac{\sigma_\epsilon^2}{1 - \phi_1^2} \begin{pmatrix} 1 & \phi_1 \\ \phi_1 & 1 \end{pmatrix} \begin{pmatrix} 1 + \phi_1\theta_1 + \theta_1^2 \\ \theta_1 \end{pmatrix} = \frac{\sigma_\epsilon^2}{1 - \phi_1^2} \begin{pmatrix} 1 + 2\phi_1\theta_1 + \theta_1^2 \\ (1 + \phi_1\theta_1)(\phi_1 + \theta_1) \end{pmatrix}.$$

Thus, the initial value of the autocorrelation coefficient is given by:

$$\rho(1) = \frac{(1 + \phi_1\theta_1)(\phi_1 + \theta_1)}{1 + 2\phi_1\theta_1 + \theta_1^2}.$$

We have:

$$\rho(\tau) = \phi_1\rho(\tau - 1).$$

### ARMA( $p, q$ ) +drift:

$$y_t = \mu + \phi_1 y_{t-1} + \phi_2 y_{t-2} + \cdots + \phi_p y_{t-p} + \epsilon_t + \theta_1 \epsilon_{t-1} + \theta_2 \epsilon_{t-2} + \cdots + \theta_q \epsilon_{t-q}.$$

Mean of ARMA( $p, q$ ) Process:  $\phi(L)y_t = \mu + \theta(L)\epsilon_t$ ,

where  $\phi(L) = 1 - \phi_1 L - \phi_2 L^2 - \cdots - \phi_p L^p$  and  $\theta(L) = 1 + \theta_1 L + \theta_2 L^2 + \cdots + \theta_q L^q$ .

$$y_t = \phi(L)^{-1} \mu + \phi(L)^{-1} \theta(L) \epsilon_t.$$

Therefore,

$$E(y_t) = \phi(L)^{-1} \mu + \phi(L)^{-1} \theta(L) E(\epsilon_t) = \phi(1)^{-1} \mu = \frac{\mu}{1 - \phi_1 - \phi_2 - \cdots - \phi_p}.$$

## 7.6 ARIMA Model

Autoregressive Integrated Moving Average (ARIMA, 自己回帰和分移動平均) Model

### ARIMA( $p, d, q$ ) Process

$$\phi(L)\Delta^d y_t = \theta(L)\epsilon_t,$$

where  $\Delta^d y_t = \Delta^{d-1}(1-L)y_t = \Delta^{d-1}y_t - \Delta^{d-1}y_{t-1} = (1-L)^d y_t$  for  $d = 1, 2, \dots$ , and  $\Delta^0 y_t = y_t$ .

### 例 : ARIMA(0,1,0) Model

Consider the model:  $\Delta y_t = y_t - y_{t-1} + \epsilon_t$ ,  $\epsilon_t \sim N(0, \sigma^2)$ ,  $y_0 = 0$ ,

which is rewritten as:  $y_t = \epsilon_t + \epsilon_{t-1} + \dots + \epsilon_1$ .

$$E(y_t) = 0, \quad \gamma(0) = V(y_t) = \sigma^2 t, \quad \gamma(\tau) = \text{Cov}(y_t, y_{t-\tau}) = E(y_t y_{t-\tau}) = \sigma^2(t - \tau),$$

which implies that  $\gamma(\tau)$  is time-dependent.  $\implies y_t$  is not stationary.

$$\rho(\tau) = \frac{\text{Cov}(y_t, y_{t-\tau})}{\sqrt{V(y_t)} \sqrt{V(y_{t-\tau})}} = \frac{t - \tau}{\sqrt{t} \sqrt{t - \tau}} = \sqrt{\frac{t - \tau}{t}}.$$

That is,  $\rho(\tau)$  gradually decreases with slow speed.

## 7.7 SARIMA Model

Seasonal ARIMA (SARIMA) Process:

### 1. SARIMA( $p, d, q$ )

$$\phi(L)\Delta^d\Delta_s y_t = \theta(L)\epsilon_t,$$

where

$$\Delta_s y_t = (1 - L^s)y_t = y_t - y_{t-s}.$$

$s = 4$  when  $y_t$  denotes quarterly date and  $s = 12$  when  $y_t$  represents monthly data.

## 7.8 Optimal Prediction

1. AR( $p$ ) Process:  $y_t = \phi_1 y_{t-1} + \cdots + \phi_p y_{t-p} + \epsilon_t$

(a) Define:

$$E(y_{t+k}|Y_t) = y_{t+k|t},$$

where  $Y_t$  denotes all the information available at time  $t$ .

Taking the conditional expectation of  $y_{t+k} = \phi_1 y_{t+k-1} + \cdots + \phi_p y_{t+k-p} + \epsilon_{t+k}$  on both sides,

$$y_{t+k|t} = \phi_1 y_{t+k-1|t} + \cdots + \phi_p y_{t+k-p|t},$$

where  $y_{s|t} = y_s$  for  $s \leq t$ .

(b) Optimal prediction is given by solving the above differential equation.

2. MA( $q$ ) Process:  $y_t = \epsilon_t + \theta_1 \epsilon_{t-1} + \cdots + \theta_q \epsilon_{t-q}$

(a) Let  $\hat{\epsilon}_T, \hat{\epsilon}_{T-1}, \dots, \hat{\epsilon}_1$  be the estimated errors.

(b)  $y_{t+k} = \epsilon_{t+k} + \theta_1 \epsilon_{t+k-1} + \cdots + \theta_q \epsilon_{t+k-q}$

(c) Therefore,

$$y_{t+k|t} = \epsilon_{t+k|t} + \theta_1 \epsilon_{t+k-1|t} + \cdots + \theta_q \epsilon_{t+k-q|t},$$

where  $\epsilon_{s|t} = 0$  for  $s > t$  and  $\epsilon_{s|t} = \hat{\epsilon}_s$  for  $s \leq t$ .

3. ARMA( $p, q$ ) Process:  $y_t = \phi_1 y_{t-1} + \cdots + \phi_p y_{t-p} + \epsilon_t + \theta_1 \epsilon_{t-1} + \cdots + \theta_q \epsilon_{t-q}$

(a)  $y_{t+k} = \phi_1 y_{t+k-1} + \cdots + \phi_p y_{t+k-p} + \epsilon_{t+k} + \theta_1 \epsilon_{t+k-1} + \cdots + \theta_q \epsilon_{t+k-q}$

(b) Optimal prediction is:

$$y_{t+k|t} = \phi_1 y_{t+k-1|t} + \cdots + \phi_p y_{t+k-p|t} + \epsilon_{t+k|t} + \theta_1 \epsilon_{t+k-1|t} + \cdots + \theta_q \epsilon_{t+k-q|t},$$

where  $y_{s|t} = y_s$  and  $\epsilon_{s|t} = \hat{\epsilon}_s$  for  $s \leq t$ , and  $\epsilon_{s|t} = 0$  for  $s > t$ .

## 7.9 Identification (識別, または, 同定)

1. Based on AIC or SBIC given  $d, s$ , we obtain  $p, q$ .

(a) AIC (Akaike's Information Criterion, 赤池の情報量基準)

$$\text{AIC} = -2 \log(\text{likelihood}) + 2k,$$

where  $k = p + q$ , which is the number of parameters estimated.

(b) SBIC (Schwarz's Bayesian Information Criterion)

$$\text{SBIC} = -2 \log(\text{likelihood}) + k \log T,$$

where  $T$  denotes the number of observations.

2. From the sample autocorrelation coefficient function  $\hat{\rho}(k)$  and the partial autocorrelation coefficient function  $\hat{\phi}_{k,k}$  for  $k = 1, 2, \dots$ , we obtain  $p, d, q, s$ .

	AR( $p$ ) Process	MA( $q$ ) Process
Autocorrelation Function	Gradually decreasing	$\rho(k) = 0,$ $k = q + 1, q + 2, \dots$
Partial Autocorrelation Function	$\phi(k, k) = 0,$ $k = p + 1, p + 2, \dots$	Gradually decreasing

(a) Compute  $\Delta_s y_t$  to remove seasonality.

Compute the autocovariance functions of  $\Delta_s y_t$ .

If the autocovariance functions have period  $s$ , we take  $(1 - L^s)$ , again.

(b) Determine the order of difference.

Compute the partial autocovariance functions every time.

If the autocovariance functions decrease as  $\tau$  is large, go to the next step.

(c) Determine the order of AR terms (i.e.,  $p$ ).

Compute the partial autocovariance functions every time.

The partial autocovariance functions are close to zero after some  $\tau$ , go to the next step.

(d) Determine the order of MA terms (i.e.,  $q$ ).

Compute the autocovariance functions every time.

If the autocovariance functions are randomly around zero, end of the procedure.

## 7.10 Example of SARIMA using Consumption Data

Construct SARIMA model using monthly and seasonally unadjusted consumption expenditure data and STATA12.

Estimation Period: Jan., 1970 — Dec., 2012 ( $T = 516$ )

## 7.11 ARCH and GARCH Models

Autoregressive Conditional Heteroskedasticity (ARCH)

Generalized Autoregressive Conditional Heteroskedasticity (GARCH)

### 1. ARCH ( $p$ ) Model

$$\epsilon_t | \epsilon_{t-1}, \epsilon_{t-2}, \dots, \epsilon_1 \sim N(0, h_t),$$

where,

$$h_t = \alpha_0 + \alpha_1 \epsilon_{t-1}^2 + \dots + \alpha_p \epsilon_{t-p}^2.$$

The unconditional variance of  $\epsilon_t$  is:

$$\sigma_\epsilon^2 = \frac{\alpha_0}{1 - \alpha_1 - \alpha_2 - \dots - \alpha_p}$$

### 2. GARCH ( $p, q$ ) Model

$$\epsilon_t | \epsilon_{t-1}, \epsilon_{t-2}, \dots, \epsilon_1 \sim N(0, h_t),$$

where

$$h_t = \alpha_0 + \alpha_1 \epsilon_{t-1}^2 + \cdots + \alpha_p \epsilon_{t-p}^2 + \beta_1 h_{t-1} + \cdots + \beta_q h_{t-q}.$$

### 3. Application to OLS (Case of ARCH(1) Model):

$$y_t = x_t \beta + \epsilon_t, \quad \epsilon_t | \epsilon_{t-1}, \epsilon_{t-2}, \dots, \epsilon_1 \sim N(0, \alpha_0 + \alpha_1 \epsilon_{t-1}^2).$$

The joint density of  $\epsilon_1, \epsilon_2, \dots, \epsilon_T$  is:

$$\begin{aligned} f(\epsilon_1, \dots, \epsilon_T) &= f(\epsilon_1) \prod_{t=2}^T f(\epsilon_t | \epsilon_{t-1}, \dots, \epsilon_1) \\ &= (2\pi)^{-1/2} \left( \frac{\alpha_0}{1 - \alpha_1} \right)^{-1/2} \exp\left( -\frac{1}{2\alpha_0/(1 - \alpha_1)} \epsilon_1^2 \right) \\ &\quad \times (2\pi)^{-(T-1)/2} \prod_{t=2}^T (\alpha_0 + \alpha_1 \epsilon_{t-1}^2)^{-1/2} \exp\left( -\frac{1}{2} \sum_{t=2}^T \frac{\epsilon_t^2}{\alpha_0 + \alpha_1 \epsilon_{t-1}^2} \right). \end{aligned}$$

The log-likelihood function is:

$$\begin{aligned} & \log L(\beta, \alpha_0, \alpha_1; y_1, \dots, y_T) \\ &= -\frac{1}{2} \log(2\pi) - \frac{1}{2} \log\left(\frac{\alpha_0}{1 - \alpha_1}\right) - \frac{1}{2\alpha_0/(1 - \alpha_1)} (y_1 - x_1\beta)^2 \\ & \quad - \frac{T-1}{2} \log(2\pi) - \frac{1}{2} \sum_{t=2}^T \log(\alpha_0 + \alpha_1(y_{t-1} - x_{t-1}\beta)^2) \\ & \quad - \frac{1}{2} \sum_{t=2}^T \frac{(y_t - x_t\beta)^2}{\alpha_0 + \alpha_1(y_{t-1} - x_{t-1}\beta)^2}. \end{aligned}$$

Obtain  $\alpha_0$ ,  $\alpha_1$  and  $\beta$  such that the log-likelihood function is maximized.

$\alpha_0 > 0$  and  $\alpha_1 > 0$  have to be satisfied.

These two conditions are explicitly included, when the model is modified to:

$$E(\epsilon_t^2 | \epsilon_{t-1}, \epsilon_{t-2}, \dots, \epsilon_1) = \alpha_0^2 + \alpha_1^2 \epsilon_{t-1}^2.$$

## Testing the ARCH(1) Effect:

- (a) Estimate  $y_t = x_t\beta + u_t$  by OLS, and compute  $\hat{\beta}$  and  $\hat{u}_t = y_t - x_t\hat{\beta}$ .
- (b) Estimate  $\hat{u}_t^2 = \alpha_0 + \alpha_1\hat{u}_{t-1}^2$  by OLS. If  $\hat{\alpha}_1$  is significant, there is the ARCH(1) effect in the error term.

This test corresponds to LM test.

## Example: GARCH(1,1) Model

```
. arch sdex l1.sdex l2.sdex, arch(1) garch(1)
(setting optimization to BHHH)
Iteration 0:   log likelihood = -5089.3558
Iteration 1:   log likelihood = -5086.7468
.....
Iteration 22:  log likelihood = -5064.9328   (backed up)
Iteration 23:  log likelihood = -5064.9328
ARCH family regression
```

Sample: 16 - 516  
 Distribution: Gaussian  
 Log likelihood = -5064.933

Number of obs = 501  
 Wald chi2(2) = 225.19  
 Prob > chi2 = 0.0000
